Prepared by a committee of the IADT:

Dr. Marie Therese Flores, Chili (Chairi); Dr. Lars Andersson, Kuwait; Dr. Jens Ove Andreasen, Denmark; Dr. Leif K. Bakland, USA; Dr. Fred Barnett, USA; Dr. Cecilia Bourguignon, France; Dr. Anthony DiAngelis, USA; Dr. Lamar Hicks, USA; Dr. Barbro Malmgren, Sweden; Dr. Asgeir Sigurdsson, Iceland; Dr. Martin Trope, USA; Dr. Mitsuhiro Tsukiboshi, Japan; Dr. Thomas von Arx, Switzerland

The guidelines represent the current best evidence based on literature research and professional opinion. As is true for all guidelines, the health care provider must apply clinical judgment dictated by the conditions present in the given traumatic situation. The IADT does not guarantee favorable outcomes from following the Guidelines, but using the recommended procedures can maximize the chances of success.

Introduction

The Guidelines contain recommendations for diagnosis and treatment of specific traumatic dental injuries using proper examination procedures:

A. Clinical Examination.
   Information about examination of traumatic injuries can be found in a number of current textbooks (links).

B. Radiographic examination
   As a routine, several angles are recommended:
   1. 90° horizontal angle, with central beam through the tooth in question
   2. Occlusal view
   3. Lateral view from the mesial or distal aspect of the tooth in question

C. Sensibility tests
   Sensibility testing refers to tests (electric pulp test or cold test) to determine the condition of the tooth pulp. Initial tests following an injury frequently give negative results, but such results may only indicate a transient lack of pulpal response. Follow-up controls are needed to make a definitive pulpal diagnosis.

D. Patient instructions
   Good healing following an injury to the teeth and oral tissues depends, in part, on good oral hygiene. Patients should be advised on how best to care for teeth that have received treatment after an injury. Brushing with a soft brush and rinsing with chlorhexidine 0.1% is beneficial to prevent accumulation of plaque and debris.

### Uncomplicated Crown Fracture

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fracture involves enamel or dentin and enamel; the pulp is not exposed. Sensibility testing may be negative initially indicating transient pulpal damage; monitor pulpal response until a definitive pulpal diagnosis can be made.</td>
<td>The 3 angulations described in the Introduction to rule out displacement or fracture of the root. Radiograph of lip or cheek lacerations is recommended to search for tooth fragments or foreign material.</td>
<td>If tooth fragment is available, it can be bonded to the tooth. Urgent care option is to cover the exposed dentin with a material such as glass ionomer or a permanent restoration using a bonding agent and composite resin. Definitive treatment for the fractured crown may be restoration with accepted dental restorative materials.</td>
</tr>
</tbody>
</table>

### Complicated Crown Fracture

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fracture involves enamel and dentin and the pulp is exposed. Sensibility testing is usually not indicated initially since vitality of the pulp can be visualized. Follow-up control visits after initial treatment includes sensibility testing to monitor pulpal status.</td>
<td>The 3 angulations described in the Introduction to rule out displacement or fracture of the root. Radiograph of lip or cheek lacerations is recommended to search for tooth fragments or foreign material. The stage of root development can be determined from the radiographs.</td>
<td>In young patients with immature, still developing teeth, it is advantageous to preserve pulp vitality by pulp capping or partial pulpotomy. This treatment is also the choice in young patients with completely formed teeth. Calcium hydroxide and MTA (white) are suitable materials for such procedures. In older patients, root canal treatment can be the treatment of choice, although pulp capping or partial pulpotomy may also be selected. If too much time elapses between accident and treatment and the pulp becomes necrotic, root canal treatment is indicated to preserve the tooth. In extensive crown fractures a decision must be made whether treatment other than extraction is feasible.</td>
</tr>
</tbody>
</table>

### Crown-Root Fracture

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fracture involves enamel, dentin and root structure; the pulp may or may not be exposed. Additional findings may include loose, but still attached, segments of the tooth. Sensibility testing is usually positive.</td>
<td>As in root fractures, more than one radiographic angle may be necessary to detect fracture lines in the root. (see Introduction for radiographic recommendations).</td>
<td>Treatment recommendations are the same as for complicated crown fractures (See above). In addition, attempts at stabilizing loose segments of the tooth by bonding may be advantageous, at least as a temporary measure, until a definitive treatment plan can be formulated.</td>
</tr>
</tbody>
</table>

### Root Fracture

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>The coronal segment may be mobile and may be displaced. The tooth may be tender to percussion. Sensibility testing may give negative results initially, indicating transient or permanent pulpal damage; monitoring the status of the pulp is recommended. Transient crown discoloration (red or grey) may occur.</td>
<td>The fracture involves the root of the tooth and is in a horizontal or diagonal plane. Fractures that are in the horizontal plane can usually be detected in the regular 90° angle film with the central beam through the tooth. This is usually the case with fractures in the cervical third of the root. If the plane of fracture is more diagonal, which is common with apical third fractures, an occlusal view is more likely to demonstrate the fracture including those located in the middle third.</td>
<td>Reposition, if displaced, the coronal segment of the tooth as soon as possible. Check position radiographically. Stabilize the tooth with a flexible splint for 4 weeks. If the root fracture is near the cervical area of the tooth, stabilization is beneficial for a longer period of time (up to 4 months). It is advisable to monitor healing for at least one year to determine pulpal status. If pulp necrosis develops, root canal treatment of the coronal tooth segment to the fracture line is indicated to preserve the tooth.</td>
</tr>
</tbody>
</table>

### Alveolar Fracture

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>The fracture involves the alveolar bone and may extend to adjacent bone. Segment mobility and dislocation are common findings. An occlusal change due to misalignment of the fractured alveolar segment is often noted. Sensibility testing may or may not be positive.</td>
<td>Fracture lines may be located at any level, from the marginal bone to the root apex. The panoramic technique is of great help in determining the course and position of fracture lines.</td>
<td>Reposition any displaced segment and then splint. Stabilize the segment for 4 weeks.</td>
</tr>
</tbody>

Favorable and Unfavorable outcomes include some, but not necessarily all of the following:

<table>
<thead>
<tr>
<th>Favorable Outcome</th>
<th>Unfavorable Outcome</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1) Asymptomatic; positive response to pulp testing; continuing root development in immature teeth. Continue to next evaluation.</td>
<td>Symptomatic; negative response to pulp testing; signs of apical periodontitis; no continuing root development in immature teeth. Root canal treatment is indicated.</td>
</tr>
<tr>
<td>(2) Positive response to pulp testing (false negative possible up to 3 months). Signs of repair between fractured segments. Continue to next evaluation.</td>
<td>Negative response to pulp testing (false negative possible up to 3 months). Clinical signs of periodontitis. Radiolucency adjacent to fracture line. Root canal treatment is indicated only to the line of fracture.</td>
</tr>
<tr>
<td>(3) Positive response to pulp testing (false negative possible up to 3 months). No signs of apical periodontitis. Continue to next evaluation.</td>
<td>Negative response to pulp testing (false negative possible up to 3 months). Signs of apical periodontitis or external inflammatory resorption. Root canal treatment is indicated.</td>
</tr>
</tbody>
</table>

2. Treatment Guidelines for Luxation Injuries

Concussion

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>The tooth is tender to touch or tapping; it has not been displaced and does not have increased mobility. Sensibility tests are likely to give positive results</td>
<td>No radiographic abnormalities.</td>
<td>No treatment is needed. Monitor pulpal condition for at least one year.</td>
</tr>
</tbody>
</table>

Subluxation

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>The tooth is tender to touch or tapping and has increased mobility; it has not been displaced. Bleeding from gingival crevice may be noted. Sensibility testing may be negative initially indicating transient pulpal damage. Monitor pulpal response until a definitive pulpal diagnosis can be made.</td>
<td>Radiographic abnormalities are usually not found.</td>
<td>A flexible splint to stabilize the tooth for patient comfort can be used for up to 2 weeks.</td>
</tr>
</tbody>
</table>

Extrusive luxation

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>The tooth appears elongated and is excessively mobile. Sensibility tests will likely give negative results. In mature teeth, pulp revascularization sometimes occurs. In immature, not fully developed teeth, pulp revascularization usually occurs.</td>
<td>Increased periodontal ligament space apically.</td>
<td>Reposition the tooth by gently reinserting it into the tooth socket. Stabilize the tooth for 2 weeks using a flexible splint. Monitoring the pulpal condition is essential to diagnose root resorption. In immature developing teeth, revascularization can be confirmed radiographically by evidence of continued root formation and pulp canal obliteration and usually return to positive response to sensibility testing. In fully formed teeth, a continued lack of response to sensibility testing should be taken as evidence of pulp necrosis together with periapical rarification and sometimes crown discoloration.</td>
</tr>
</tbody>
</table>

3
### Lateral luxation

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>The tooth is displaced, usually in a palatal/lingual or labial direction. It will be immobile and percussion usually gives a high, metallic (ankylosic) sound. Sensibility tests will likely give negative results. In immature, not fully developed teeth, pulpal revascularization usually occurs.</td>
<td>The widened periodontal ligament space is best seen on eccentric or occlusal exposures.</td>
<td>Reposition the tooth with forceps to disengage it from its bony lock and gently reposition it into its original location. Stabilize the tooth for 4 weeks using a flexible splint. Monitor the pulpal condition. If the pulp becomes necrotic, root canal treatment is indicated to prevent root resorption. In immature, developing teeth, revascularization can be confirmed radiographically by evidence of continued root formation and possibly by positive sensibility testing. In fully formed teeth, a continued lack of response to sensibility testing indicates pulp necrosis, along with periapical rarefaction and sometimes crown discoloration.</td>
</tr>
</tbody>
</table>

### Intrusive luxation

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>The tooth is displaced axially into the alveolar bone. It is immobile and percussion may give a high, metallic (ankylosic) sound. Sensibility tests will likely give negative results. In immature, not fully developed teeth, pulpal revascularization may occur.</td>
<td>The periodontal ligament space may be absent from all or part of the root.</td>
<td>1. <strong>Teeth with incomplete root formation</strong>: Allow spontaneous repositioning to take place. If no movement is noted within 3 weeks, recommend rapid orthodontic repositioning. 2. <strong>Teeth with complete root formation</strong>: The tooth should be repositioned either orthodontically or surgically as soon as possible. The pulp will likely become necrotic and root canal treatment using a temporary filling with calcium hydroxide is recommended to retain the tooth.</td>
</tr>
</tbody>
</table>

### Clinical situation (3.1c) Treatment

<table>
<thead>
<tr>
<th>Clinical situation</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Closed apex</strong>&lt;br&gt;Extra-oral dry time longer than 60 minutes</td>
<td>Delayed replantation has a poor long term prognosis. The periodontal ligament will be necrotic and not expected to heal. The goal in doing delayed replantation is to promote alveolar bone growth to encapsulate the replanted tooth. The expected eventual outcome is ankylosis and resorption of the root. In children below the age of 15, if ankylosis occurs, and when the infraposition of the tooth crown is more than 1mm, it is recommended to perform decoronation to preserve the contour of the alveolar ridge. &lt;br&gt;The technique for delayed replantation is:&lt;br&gt;1. Remove attached necrotic soft tissue with gauze.&lt;br&gt;2. Root canal treatment can be done on the tooth prior to replantation, or it can be done 7-10 days later as for other replantations.&lt;br&gt;3. Remove the coagulum from the socket with a stream of saline. Examine the alveolar socket. If there is a fracture of the socket wall, reposition it with a suitable instrument.&lt;br&gt;4. Immerse the tooth in a 2% sodium fluoride solution for 20 minutes.&lt;br&gt;5. Replant the tooth slowly with slight digital pressure. Suture gingival laceration. Verify normal position of the replanted tooth clinically and radiographically.&lt;br&gt;6. Stabilize the tooth for 4 weeks using a flexible splint.</td>
</tr>
</tbody>
</table>

### Clinical situation (3.2a) Treatment

<table>
<thead>
<tr>
<th>Clinical situation</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Open Apex</strong>&lt;br&gt;The tooth has already been replanted prior to the patient arriving in the dental office or clinic.</td>
<td>Clean the area with water spray, saline or chlorhexidine. Do not extract the tooth. Suture gingival lacerations if present. Verify normal position of the replanted tooth both clinically and radiographically. Apply a flexible splint for up to 2 weeks. &lt;br&gt;Administer systemic antibiotics. For children 12 years and younger: Penicillin V at an appropriate dose for patient age and weight. For children older than 12 years of age, where there is little risk for tetracycline discoloration: Tetracycline (Doxycycline 2x per day for 7 days at appropriate dose for patient age and weight).&lt;br&gt;Refer the patient to a physician for evaluation of need for a tetanus booster if avulsed tooth has contacted soil or tetanus coverage is uncertain. &lt;br&gt;The goal for replanting still-developing (immature) teeth in children is to allow for possible revascularization of the tooth pulp. If that does not occur, root canal treatment may be recommended – see <em>Follow-up procedures for avulsed permanent teeth</em> below. &lt;br&gt;Patient instructions&lt;br&gt;Soft diet for up to two weeks.&lt;br&gt;Brush teeth with a soft toothbrush after each meal.&lt;br&gt;Use a chlorhexidine (0.1%) mouth rinse twice a day for 1 week. &lt;br&gt;Follow-up&lt;br&gt;See <em>Follow-up procedures for avulsed permanent teeth</em> below.</td>
</tr>
</tbody>
</table>

3.2 Treatment guidelines for avulsed permanent teeth with open apex.
### Clinical situation (3.2b) Treatment

<table>
<thead>
<tr>
<th>Open Apex</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>The tooth has been kept in special storage media (Hank’s balanced Salt Solution), milk, saline, or saliva. The extra-oral dry time is less than 60 minutes.</td>
<td>If contaminated, clean the root surface and apical foramen with a stream of saline. Remove the coagulum from the socket with a stream of saline and then replant the tooth. If available, cover the root surface with minocycline hydrochloride microspheres (Arestin™, OraPharma Inc.) before replanting the tooth.</td>
</tr>
</tbody>
</table>

Examine the alveolar socket. If there is a fracture of the socket wall, reposition it with a suitable instrument. Replant the tooth slowly with slight digital pressure. Suture gingival lacerations, especially in the cervical area. Verify normal position of the replanted tooth clinically and radiographically. Apply a flexible splint for up to 2 weeks.

Administer systemic antibiotics. For children 12 years and younger: penicillin V at appropriate dose for patient age and weight. For children older than 12 years of age, where there is little risk for tetracycline discoloration: Tetracycline (Doxycycline 2x per day for 7 days at appropriate dose for patient age and weight).

Refer to physician for evaluation of need for a tetanus booster if avulsed tooth has contacted soil or tetanus coverage is uncertain.

The goal for replanting still-developing (immature) teeth in children is to allow for possible revascularization of the tooth pulp. If that does not occur, root canal treatment may be recommended – see ‘Follow-up procedures for avulsed permanent teeth’ below.

### Patient instructions
- Soft diet for up to two weeks.
- Brush teeth with a soft toothbrush after each meal.
- Use a chlorhexidine (0.1%) mouth rinse twice a day for 1 week.

### Follow-up
- See ‘Follow-up procedures for avulsed permanent teeth’ below.

### Clinical situation (3.2c) Treatment

<table>
<thead>
<tr>
<th>Open Apex</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extra-oral dry time longer than 60 minutes</td>
<td>Delayed replantation has a poor long-term prognosis. The periodontal ligament will be necrotic and not expected to heal. The goal in doing delayed replantation of immature teeth in children is to maintain alveolar ridge contour. The eventual outcome is expected to be ankylosis and resorption of the root. It is important to recognize that if delayed replantation is done in a child, future treatment planning must be done to take into account the occurrence of tooth ankylosis and the effect of ankylosis on the alveolar ridge development. If ankylosis occurs, and when the infraposition of the tooth crown is more than 1mm, it is recommended to perform decoronation to preserve the contour of the alveolar ridge.</td>
</tr>
</tbody>
</table>

The technique for delayed replantation is:

1. Remove attached necrotic soft tissue with gauze.
2. Root canal treatment can be done on the tooth prior to replantation through the open apex.
3. Remove the coagulum from the socket with a stream of saline. Examine the alveolar socket. If there is a fracture of the socket wall, reposition it with a suitable instrument.
4. Immerse the tooth in a 2% sodium fluoride solution for 20 minutes.
5. Replant the tooth slowly with slight digital pressure. Suture gingival laceration. Verify normal position of the replanted tooth clinically and radiographically.
6. Stabilize the tooth for 4 weeks using a flexible splint.

Administration of systemic antibiotics, see 3.1b.

Refer the patient to physician for evaluation of need for a tetanus booster if the avulsed tooth has contacted soil or tetanus coverage is uncertain.

### Patient instructions
- Soft diet for up to two weeks.
- Brush teeth with a soft toothbrush after each meal.
- Use a chlorhexidine (0.1%) mouth rinse twice a day for 1 week.

### Follow-up
- See ‘Follow-up procedures for avulsed permanent teeth’ below.
Follow-up procedures for avulsed permanent teeth

Root canal treatment
If root canal treatment is indicated (teeth with closed apex), the ideal time to begin treatment is 7-10 days post-replantation. Calcium hydroxide is recommended for intra canal medication for up to one month followed by root canal filling with an acceptable material. An exception is a tooth that has been dry for more than 60 minutes before replantation – in such cases the root canal treatment may be done prior to replantation.

In teeth with open apexes, that have been replanted immediately or kept in appropriate storage media, pulp revascularization is possible. Root canal treatment should be avoided unless there is clinical and radiographic evidence of pulp necrosis.

Clinical control
Replanted teeth should be monitored by frequent controls during the first year (once a week during the first month, 3, 6, and 12 months) and then yearly thereafter. Clinical and radiographic examination will provide information to determine outcome. Evaluation may include the findings described below.

Favorable outcome
1. **Closed apex**: Asymptomatic, normal mobility, normal percussion sound. No radiographic evidence of resorption or periradicular osteitis; the lamina dura should appear normal.
2. **Open apex**: Symptomatic, normal mobility, normal percussion sound. Radiographic evidence of arrested or continued root formation and eruption. Pulp canal obliteration is the rule.

Unfavorable outcome
1. **Closed apex**: Symptomatic, excessive mobility or no mobility (ankylosis) with high pitched percussion sound. Radiographic evidence of resorption (inflammatory, infection-related resorption, or ankylosis-related replacement resorption).
2. **Open apex**: Symptomatic, excessive mobility or no mobility (ankylosis) with high pitched percussion sound. In the case of ankylosis, the crown of the tooth will appear to be in an infra-occlusal position. Radiographic evidence of resorption (inflammatory, infection-related resorption, or ankylosis-related replacement resorption).

Splinting guidelines for tooth/bone fractures and luxated/avulsed teeth

Guidelines for the management of traumatic injuries in the primary dentition  
2007

Prepared by a committee of the IADT:

Dr. Marie Therese Flores, Chili (Chairi); Dr. Lars Andersson, Kuwait; Dr. Jens Ove Andreasen, Denmark; Dr. Leif K. Bakland, USA; Dr. Fred Barnett, USA; Dr. Cecilia Bourguignon, France; Dr. Anthony DiAngelis, USA; Dr. Lamar Hicks,
USA; Dr. Barbro Malmgren, Sweden; Dr. Asgeir Sigurdsson, Iceland; Dr. Martin Trope, USA; Dr. Mitsuhiro Tsukiboshi, 
Japan; Dr. Thomas von Arx, Switzerland

The guidelines represent the current best evidence based on literature research and professional opinion. As is true 
for all guidelines, the heal care provider must apply clinical judgment dictated by the conditions present in the given 
traumatic situation. The IADT does not guarantee favorable outcomes from following the Guidelines, but using the 
recommended procedures can maximize the chances of success.

Introduction

The management of traumatic injuries to primary teeth differs from that used for permanent teeth. It is important to 
keep in mind that there is close relationship between the apex of the root of the injured primary tooth and the 
underlying permanent tooth germ. Tooth malformation, impacted teeth and eruption disturbances in the developing 
permanent dentition are some of the consequences that can occur following severe injuries to primary teeth and/or 
alveolar bone. Because of this potential sequelae treatment selection should such as to avoid any additional risks of 
further damaging the permanent successors. The child’s maturity and ability to cope with the emergency situation, the 
time for shedding of the injured tooth and the occlusion, are important factors that influence treatment selection. The 
Guidelines contain recommendations for diagnosis and treatment of traumatic injuries in the primary dentition for 
caries-free or sound primary teeth using proper examination procedures:

A. Clinical Examination

Information about examination of traumatic injuries in the primary dentition can be found in a number of current 
textbooks (links).

B. Radiographic examination

Depending on the child’s ability to cope with the procedure and the type of injury suspected, several angles are 
recommended:

1. 90° horizontal angle, with central beam through the tooth in question (size 2 film, horizontal view)
2. Occlusal view (size 2 film, horizontal view)
3. Extra-oral lateral view of the tooth in question, which is useful to reveal the relationship between the apex of 
   the displaced tooth and the permanent tooth germ as well as the direction of dislocation (size 2 film, vertical 
   view).

C. Patient instructions

Good healing following an injury to the teeth and oral tissues depends, in part, on good oral hygiene. Parents should 
be advised on how best to care for their children’s primary teeth after an injury. Brushing with a soft brush after each 
meal and applying chlorhexidine (0.1%) topically to the affected area(s) with cotton swabs twice a day for one week, is 
beneficial to prevent accumulation of plaque and debris. Along with recommending a soft diet for 10 to 14 days, 
restrict the use of pacifier. If there are associated lip injuries, use of lip balm during the healing period will avoid 
dryness.
Parents should be further advised about possible complications that may occur, like swelling, increased mobility or fistula. Children may not complain about pain; however, infection may be present and parents should watch for signs such as swelling of the gums and bring the children in for treatment.

Document in the chart that the parent has been informed about possible complications in the development of the permanent teeth, especially following intrusion, avulsion and alveolar fracture injuries sustained in children under 3 years of age.

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Uncomplicated Crown Fracture</td>
<td>Fracture involves enamel or dentin and enamel; the pulp is not exposed.</td>
<td>The relation between the fracture and the pulp chamber will be disclosed.</td>
</tr>
<tr>
<td>Complicated Crown Fracture</td>
<td>Fracture involves enamel and dentin and the pulp is exposed.</td>
<td>One exposure is useful to rule out the extent of fracture and stage of root development.</td>
</tr>
<tr>
<td>Crown-Root Fracture</td>
<td>Fracture involves enamel, dentin and root structure; the pulp may or may not be exposed. Additional findings may include loose, but still attached, fragments of the tooth. There is minimal to moderate tooth displacement</td>
<td>In laterally positioned fractures, the extent in relation to the gingival margin can be seen.</td>
</tr>
<tr>
<td>Root Fracture</td>
<td>The coronal fragment is mobile and may be displaced.</td>
<td>The fracture is usually located mid-root or in the apical third.</td>
</tr>
<tr>
<td>Alveolar Fracture</td>
<td>The fracture involves the alveolar bone. The tooth-containing segment is mobile and usually displaced. Occlusal interference is often noted.</td>
<td>The horizontal fracture line to the apices of the primary teeth and their permanent successors will be disclosed. A lateral radiograph may also give information about the relation between the two dentitions and if the segment is displaced in labial direction.</td>
</tr>
</tbody>
</table>
2. Treatment Guidelines for Luxation Injuries

**Concussion**

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>The tooth is tender to touch; it has no increased mobility or sulcular bleeding.</td>
<td>No radiographic abnormalities. Normal periodontal space.</td>
<td>No treatment is needed. Observation.</td>
</tr>
</tbody>
</table>

**Subluxation**

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>The tooth has increased mobility but has not been displaced. Bleeding from gingival crevice may be noted.</td>
<td>Radiographic abnormalities are usually not found. Normal periodontal space.</td>
<td>No treatment is needed. Observation.</td>
</tr>
</tbody>
</table>

**Extrusive luxation**

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>The tooth appears elongated and is excessively mobile.</td>
<td>Increased periodontal ligament space apically.</td>
<td>Treatment decisions are based on the degree of displacement, mobility, root formation and the ability of the child to cope with the emergency situation. For minor extrusion (&lt;3mm) in an immature developing tooth, careful repositioning or leaving the tooth for spontaneous alignment are acceptable treatment options. Extraction is the treatment of choice for severe extrusion in a fully formed primary tooth.</td>
</tr>
</tbody>
</table>

**Lateral luxation**

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>The tooth is displaced, usually in a palatal/lingual direction. It will be often immobile.</td>
<td>Increased periodontal ligament space apically is best seen on the occlusal exposure.</td>
<td>If there is no occlusal interference, as is often the case in anterior open bite, the tooth is allowed to reposition spontaneously. When there is occlusal interference, with the use of local anesthesia, the tooth can be gently repositioned by combined labial and palatal pressure. In severe displacement, when the crown is dislocated in a labial direction, extraction is the treatment of choice. If minor occlusal interference, slight grinding is indicated.</td>
</tr>
</tbody>
</table>

**Intrusive luxation**

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>The tooth is usually displaced through the labial bone plate, or can be impinging upon the succedaneous tooth bud.</td>
<td>When the apex is displaced toward or through the labial bone plate, the apical tip can be visualized and appears shorter than the contra lateral tooth. When the apex is displaced towards the permanent tooth germ, the apical tip cannot be visualized and the tooth appears elongated.</td>
<td>If the apex is displaced toward or through the labial bone plate, the tooth is left for spontaneous repositioning. If the apex is displaced into the developing tooth germ, extract.</td>
</tr>
</tbody>
</table>

**Avulsion**

<table>
<thead>
<tr>
<th>Clinical findings</th>
<th>Radiographic findings</th>
<th>Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>The tooth is completely out of the socket.</td>
<td>A radiographic examination is essential to ensure that the missing tooth is not intruded</td>
<td>It is not recommended to replant avulsed primary teeth.</td>
</tr>
</tbody>
</table>

IX. Follow-up
**Examination Form For Trauma Patients**

**Patient Name**
*Clinicians should use their standard office form to record medical history.*

**Neurologist Assessment**

Does the patient have or had the patient had any of the following symptoms since the injury?

- [ ] nausea
- [ ] headache
- [ ] vomiting

Did the patient lose consciousness?  [ ] Yes  [ ] No  If so, for how long? ________________

Can the patient remember what happened  [ ] before  [ ] during  [ ] after the accident?

Is there:  [ ] double vision  [ ] limited eye movement  [ ] abnormal pupillary reflex

**History of the Injury**

Date: __________ Time: __________ Place where injury happened: ________________________________

How did the injury occur? ________________________________________________________________

____________________________________________________________________________________

Was treatment provided elsewhere?  [ ] Yes  [ ] No  If yes, describe: _____________________________

____________________________________________________________________________________

Chief complaint: ______________________________________________________________________

Pain  [ ] Yes  [ ] No  Location of pain (tooth/teeth): ________________________________

Type of pain (percussion, biting, cold) ____________________________________________________

Characteristics of pain (constant, episodic) ________________________________________________

Were the teeth avulsed?  [ ] Yes  [ ] No

If so:

Where were the teeth found? ______________________________________________________________

When were the teeth found? _____________________________________________________________

Were the teeth dirty?  [ ] Yes  [ ] No

How were the teeth stored? ______________________________________________________________

Were the teeth rinsed prior to replantation?  [ ] Yes  [ ] No  If so, with what ________________

When were the teeth replanted? _________________________________________________________

Was tetanus antitoxoid given?  [ ] Yes  [ ] No

Were antibiotics given?  [ ] Yes  [ ] No  If so, type and dosage ______________________________

____________________________________________________________________________________
Extraoral Examination

Is the patient’s general condition affected?  ☐ Yes  ☐ No

Pulse and blood pressure ______________________________________________________

Objective findings within the head and neck?  ☐ Yes  ☐ No  If yes, type and location: __________

____________________________________________________________________________________

Bleeding from the: ☐ nose  ☐ ear

Palpable signs of fracture of facial skeleton?  ☐ Yes  ☐ No  If yes, location of fracture: __________

____________________________________________________________________________________

Intraoral Examination

Injury to the oral mucosa  ☐ Yes  ☐ No  Location ________________________________

Injury to the gingival  ☐ Yes  ☐ No  Location ________________________________

Tooth fracture  ☐ Yes  ☐ No  Location ________________________________

Alveolar fracture  ☐ Yes  ☐ No  Location ________________________________

Tooth discoloration  ☐ Yes  ☐ No  Location ________________________________

Dental Examination

General condition of dentition  ☐ Good  ☐ Fair  ☐ Poor

Caries  ☐ Minimal  ☐ Moderate  ☐ Extensive

Periodontal status  ☐ Good  ☐ Fair  ☐ Poor

Horizontal occlusal relationship  ☐ Underbite  ☐ Overbite  ☐ Normal

Vertical occlusal relationship  ☐ Deep  ☐ Open  ☐ Normal
